Abstract

PURPOSE:To automatically set the access timing of a memory by changing successively the set value of a register by a program and giving an access to memory based on the set value obtained when the coincidence of comparison is obtained between read data and write data.

CONSTITUTION:An optimum value is set at each of registers 21-24 and a memory (RAM 1) receives an access based on each set value of these registers to write and read the test data. These test write and read data are compared with each other for each access action carried out based on each set value. When read data are compared with each other for each access action carried out based on each set value. When the coincidence is obtained between write and read data of the memory (RAM 1), the relevant value is set the coincidence is obtained between while and read data of the memory (Now) 1), the relevant value is set at the registers 21-24 respectively as the final set value. Then the access timing is decided based on said at the registers 21-24 respectively as the final set value and the memory (RAM 1) receives accesses in this timing for prescribed data writing and final set value and the memory (RAM 1) receives accesses in this timing for prescribed data writing and reading operations. In such a way, the access timing of the RAM can be automatically set with no intervention of man power.

ノモリアクセスタイミング設定方式

メモリのアクセスを行う論理問路において、ブ ログラムによって任意に値を設定できるレジスタ を設け、このレジスタへの設定値をプログラムに よって嬢々に変えでゆき、メモリへのテストデー タの書き込み、領出し、書込みデータと読出しデ - タとの比較を繰り返して行い、比較の結果が一 及した時の設定値モレジスタに設定しておき、こ の設定値に基づいてメモリのアクセスを行うこと を特徴とするメモリアクセスタイミング設定方式。 3. 発明の評価な政明

(産業上の利用分野)

この発明はデータ処理装置などに備えられるう ンダムアクセスメモリ (以下RAMと称す) のて クセスタイミングを設定するためのメモリアクセ

スタイミング設定方式に関するものである。

(従来の技術)

第6回は従来のメモリアクセスタイミング設定 方式を採用した論理図器のブロック図である。図 において、 i はRAM(グイナミックRAMを用 いた場合を例にとる)、2はアドレスマルチプレ クサ、3 はRAM1とアドレスマルテプレクサ 2 とを接続するマルチプレクスド・アドレス・パス、 4 はアドレスマルテプレクサ 2 に接続されるアド レスパス、5はRAMlに接続されるデータパス、 6はメモリ制御リングである。また、1はローア ドレスセレクト信号 (RAS信号) 生成用のフリ ップフロップ(以下RAS用フリップフロップと 称す)、目はカラムアドレスセレクト体号(CA S信号)生展用のフリップフロップ(以下CAS 用フリップフロップと称す)、9はカラムセレク トは号 (COLSは号) 生成用のフリップフロッ プ(以下COLS用フリップフロップと称す)、 10 HANDY-1. 11, 12, 1340RY ->. 14. 15. 16 UNORY->. 17. 18.19.20はメモリ制御リング6のどの出 力を使用するかを選択するためのジャンパ嬢であ る。なお、説明を簡単にするためRAMIのリフ レッシュ用の位理回路は省略する。

次に動作について模別す。説明の中で「1」は 有寒もしくはハイレベルを、「0」は非有寒もし くはローレベルを意味する。メモリ制御リング 6 はラインししのメモリアクセスモードは号が「1」 になるとイネーブルされて動作可能状態となり、 ラインL2の基本クロックに同期して出力T C. $T \; 1 \; , \; \cdot \; \cdot \; \cdot \; , \; T \; k \; , \; \cdot \; \cdot \; \cdot \; , \; T \; \ell \; , \; \cdot \; \cdot \; \cdot \; ,$ Tm. · · · , Tn. · · · , Te-1, Te i それぞれ頃に「1」になるという形で状態が選移 する。また、メモリアクセスモードは号が「0; になると、メモリ製御リング6の出力TO~Te は全て「0」になる。各フリップフロップ7、8. 9 はラッチした信号を各出力幾子 1 から出力し、 そのラッチした信号の反転信号を各出力補子りか ら出力する。RAMIの増子RAS、CAS、 WEにそれぞれ与えられるRASは号。CASは 号、WE信号は「1」で有意とする。また、この 従来例の場合、ジャンパ練17、18、19、

20の設定は人手により行い、メモリ制御リング 6の出力Tk、Tt. Tm. Tnがそれぞれ選択 されたものとする。

ここで深く図に示すタイミングチャートを参照してRAM1への審込み動作を例にとって説明する。メモリアクセスが開始されると、ラインし1のメモリアクセスモード信号及びラインし3のライトモード信号が「1」になる。この時、アドレスがアドレスバス4に与えられ、アドレスがス4に与えられ、アドレスが正かりつってによりローアドレスが選択されてマルチプレクスド・アドレス・バス3上に出力される。またられる。

このようなローアドレス及び書込みデークが与えられ、メモリ制御リング6は前述したようにラインし1のメモリアクセスモード信号が「1」になっているので動作を開始し、出力下り、 T1. ・・・ Tkが順次「1」になるという形で状態が選移する。そして出力Tkが「1」になると、メンパ減17及びORゲート11を経由してRA

S用フリップフロップ1の箱子口に「1」の出力 丁kが与えられ、メモリ制御リング6の出力Tk + l が「l 」になる時、R A S 用フリップフロッ プイの出力端子!から出力されるRAS信号が 「1」になる。また、この時、RAS用フリップ フロップ7の出力箱子0から出力される反転出力 は「0」となり、これによりNORゲート14の 出力が「1」、ORゲート11の出力が「1」と なって、メモリ制御リング6の状態が進んでも RAS用フリップフロップ1の出力、すなわち RAS信号は「1」にホールドされる。また、メ モリ制御リングもの「1」の出力がTIからTI + 1 に過移した時、前記と同様な動作によりCO LS用フリップフロップ3の出力であるCOLS 信号が「1」になりホールドされる。このCOL 5億号により、アドレスマチブレクサ2はマルチ プレクスド・アドレス・パスろにカラムアドレス を出力し、また、ANDゲート10の出力、すな わちRAMIの路子WEに与えられるWE信号が 「1」となり、RAM1はライトモードとなる。

また、メモリ制御リング5の「1」の出力がTm からTm+lに通移した時、胸配と関係な動作に よりCAS用フリップフロップ8の出力、すなわ 5CASは号は「1」になりホールドされる。以 上のようにRAS信号、CAS信号、WE信号、 COLS信号が全て「L」となって、RAM1へ の書込み条件が全て擽い、データの書込み曲作が 行われ、メモリ製造リング6の状態が進み、出力 Tn-1が「1」になった時点で書込み動作が完 了する。メモリ製剤リング6の出力Tコ、すなわ ちラインし4のメモリアクセス完了信号が「1」 になり、次に出力Tn+1が「1」になろうとす るところでラインレーのメモリアクセスモード住 号及びラインL3のライトモード信号が「0」に なり、また、NORゲート14.15.16及び ORゲート11、12、13の出力が「0」にな るので、RAS信号、CAS信号、COLS信号 が「O」になり、RAM1への書込み動作が終了 する。なお、第4回に示すTWは、RAM1への 制御は号(メモリアクセスモード信号、ライトモ ード信号、RAS信号、COLS信号、CAS信号WE信号)によるライトモード条件成立期間である。

(発明が解決しようとする問題点)。

従来のメモリアクセスタイミング設定方式においては、RAMへのアクセスタイミングを決定する部分がジャンパ嬢による設定であったため、モ

この発明は上記のような問題点を解析するためになされたもので、RAMのアクセスタイミングの設定を人手の介入なしに自動的に行い、RAMの性能を十分に引き出すことができ、位領性を向上させることができるメモリアクセスタイミング設定方式を提供することを目的とする。

(問題点を解決するための手段)

この発明に振るメモリアクセスタイミング設定 方式は、メモリ (RAM1) のアクセスを行う論 理国路において、プログラムによって任意に値を

設定できるレジスタ21、22、23、24を設け、このレジスタ21、22、23、24への設定値をプログラムによって増々に変えてゆき、ままり(RAM1)へのチストデータの書込みを設出し、書込みデータと設出しデータとの比較をしており返し、比較の結果が一致した時の設定値をレンスタ21、22、23、24に設定しておき、この設定値に基づいてメモリ(RAM1)のアクセスを行うことを特徴とするものである。

(作用)

この発明に係るレジスタ21、22、23、24にはプログラムによって任意の値が設定され、メモリ(RAM1)は設定された各設定値に基づいてアクセスされ、テストデータの書込みデータとは各設定値に基づいたアクセストデーをは大きれ、メモリ(RAM1)の書込みデータと禁止しデータとか一致した時、その値はよりの設定値としてレジスタ21、22、23、24に設定され、その後はその最終の設定値に基づい

てアクセスタイミングが決められ、メモリ (R A M1) はそのアクセスタイミングでアクセスされ、 所定のデータの普込み、数出し動作を行う。

(発明の実施例)

以下この発明の一実施例を図に基づいて説明す る。張1回はこの発明の一実施例に係るメモリア クセスタイミング設定方式を提用した論理回路の ブロック図である。第1図において、第6図に示 **丁祿成要素に対応するものには同一の参照符を付** し、その説明を省略する。第1回において、21 はRAS信号生成ティミングを決めるためのレジ スタ(以下RAS用レジスタと称す)、22は COLS信号生収タイミングを決めるためのレジ スタ(以下COLS用レジスタ)、23はCAS 信号生成タイミングを決めるためのレシスタ(以 下CAS用レジスタと称す)、24はメモリアク セス完了信号生成タイミングを決めるためのレジ スタ(以下CPT用レジスタと称す)、25. 26. 27. 28はメモリ関係リング6のヒ+1 個ある出力T0~Te の内の1個を選択して出力 するセレクタである。

Details

Name of Invention 1. Method for Setting Memory Access Timing

Patent Claims 2.

A method for setting memory access timing in a logical circuit that accesses memory, characterized by the provision of a register for which a variety of values can be set by a program, by repetitively having the value set in said register be changed sequentially by the program and performing test writes to the memory and test reads from the memory where the data that is written is compared to the data that is read, by setting to the register the setting that was in effect when the results of the comparison matched, and by accessing the memory based on said setting.

3. Detailed Explanation of the Invention

[Area of Application in Industry]

This invention pertains to a method for setting the memory access timing in order to set the access timing for random access memory (hereinafter abbreviated "RAM") that is equipped in, for example, data processing devices.

[Prior Art]

Figure 6 shows a block diagram of the logic circuits that use the conventional memory access timing set method. In the figure, 1 is RAM (using the example where a dynamic RAM is used), 2 is an address multiplexer, 3 is a multiplexed address bus connecting the RAM 1 with the address multiplexer 2, 4 is an address bus connected to the address multiplexer 2, 5 is a data bus connected to the RAM 1, and 6 is a memory control ring. In addition, 7 is a flipflop for generating the row address select signal (RAS signal), hereinafter abbreviated "RAS flipflop," 8 is a flipflop for generating the column address select signal (CAS signal), hereinafter abbreviated "CAS flipflop," 9 is a flipflop for generating the column select signal (COLS signal), hereinafter abbreviated "COLS flipflop," 10 is an AND gate, 11, 12, and 13 are OR gates, 14, 15, and 16 are NOR gates, and 17, 18, 19, and 20 are jumper lines for selecting the output from the memory control ring 6 that is to be used. Additionally, for simplicity in the explanation, the logic circuits for refreshing the RAM 1 are not shown.

The operation of this method is described below. In this explanation, "1" indicates either the active level or the high logic level, while "0" indicates the inactive level or the low logic level. The memory control ring 6 is enabled and placed in an operational state when the memory access mode signal of line L1 goes to "1," and, synchronized to the master clock on line L2, the outputs T0, T1, ..., Tk, ..., T1, ..., Te-1, Te are sequentially set to "1" in the state transitions. When the memory access mode signal is "0," all outputs T0 to Te from the memory control ring 6 go to "0." The respective flipflops 7, 8, and 9 each output their latched signals from the output terminal 1 on each, and output the inverse of the latched signal on output terminal 0 of each. The RAS signal, CAS signal, and WE signal applied, respectively, to the RAS, CAS, and WE terminals of RAM 1 are each active at "1." In addition, in this conventional example, jumper lines 17, 18, 19, and 20 are set by hand, selecting, respectively, outputs Tk, Tl, Tm, and Tn of the memory control ring 6.

Below will be explained an example of an operation to write to the RAM 1, referencing the timing chart shown in Figure 4. When the memory access commences, both the memory access mode signal on Line L1 and the write mode signal on Line 3 both go to "1." At this time, the address is applied to the address bus 4, the row address is selected by the address multiplexer 2 and is output on the multiplexed address bus 3. At this time the write data is applied to data bus 5.

In this way, the row address and write data are applied, and, as described above, the memory access mode signal of line L1 is at "1," so the memory control ring 6 commences operations, and there are state transitions so that outputs T0, T1, ... Tk sequentially go to "1." When Tk goes to "1," the "1" output Tk is applied to terminal D of the RAS flipflop 7 through the jumper line 17 and OR gate 11, and when output Tk + 1 of memory control ring 6 goes to "1," the RAS signal that is output from output terminal 1 of the RAS flipflop 7 goes to "1." In addition, at this time the inverted signal that is output from the output terminal 0 of the RAS flipflop 7 goes to "0," causing the output of the NOR gate 14 to go to "1," and the output of the OR gate 11 to go to "1," causing the output of the RAS flipflop 7, or in other words the RAS signal, to be held at "1" even if the memory control ring 6 status advances. When the "1" output of the memory control ring 6 transitions from TI to TI + 1, the same operation as described above causes the COLS signal, which is the output of the COLS flipflop 9, to be held at "1." This COLS signal causes the address multiplexer 2 to output the column address to the multiplexed address bus 3, and the output of the AND gate 10, or in other words the WE signal that is applied to the RAM 1 terminal WE, goes to "1," placing RAM 1 in write mode. When the "1" output of the memory control ring 6 transitions from Tm to Tm + 1, a operation similar to what was described above causes the output of the CAS flipflop 8, or in other words the CAS signal, to be held at "1." As described above, the RAS signal, the CAS signal, the WE signal, and the COLS signal all go to "1," putting all conditions in place to write to the RAM 1; hence the data write operation is performed, the status of the memory control ring 6 advances, and the write operation is concluded at the point in time where the output Tn - 1 goes to "1." When the output Tn of the memory control ring 6, or in other words the memory access complete signal on line 4, goes to "1" followed by the output Tn + 1 going to "1," the memory access mode signal on line L1 and the write mode signal on line L3 both go to "0," causing the outputs of the NOR gates 14, 15, and 16, along with the outputs of the OR gates 11, 12, and 13 to go to "0"; consequently, the RAS signal, the CAS signal, and the COLS signal all go to "0," completing the operation for writing to the RAM 1. Note that TW shown in Figure 4 is the period over which the write mode conditions are fulfilled by the control signals to the RAM 1 (i.e., the memory access mode signal, the write mode signal, the RAS signal, the COLS signal, the CAS signal, and the WE signal).

On the other hand, in the operations to read from the RAM 1, as shown in Figure 5, the write mode signal and the WE signal go to "0," and at the point in time when the output Tn - 1 of the memory control ring 6 ceases to output "1," or in other words, at the point in time when the output Tn goes to "1," the output data that is read from the RAM 1 is assumed to be set, and with the output Tn, the data on the data bus 5 is accepted. At this time, when, in operations similar to the write operations described above the output Tn + 1 of the memory control ring 6 is to go to "1," all control signals become inactive and the operations to read from the

RAM 1 are terminated. Note that the TR shown in Figure 5 is the period of time over which the control signals to the RAM 1 fulfill the read mode conditions.

[Problems Solved by this Invention]

In the conventional method for setting the memory access timing, the part that sets the RAM access timing is set by jumper lines, and thus it requires a manual intervention to set the jumper lines. Additionally, generally RAMs have a variety of different access times, and when the type of RAM that is used is changed it is necessary to change the settings of the jumpers in order to change the access timing, and, as a result, the RAM cannot be accessed correctly if the setting is incorrect or there may also be the problem that, even if RAM that can operate at high speeds is used, the actual performance of the RAM will not be good if the access timing used is for low speed RAM.

This invention was created in order to solve the types of problems described above, and its objective is to provide a method of setting the memory access timing that automatically sets the access timing without any manual intervention, making it possible to exploit the full capabilities of the RAM and to improve reliability.

[Method by Which the Problems are Solved]

The method of setting the memory access timing in this invention is characterized. by the logic circuits that access the memory (RAM 1) being equipped with registers 21, 22, 23, and 24 that can be set to a variety of values by a program, where the values that are set to these registers 21, 22, 23, and 24 are repetitively changed sequentially by the program at which time test data is written to and read from the memory (RAM 1) and comparisons are made between the write data and the read data where the values that were set when the results of the comparison indicates a match are set to registers 21, 22, 23, and 24, so that the access to the memory (RAM 1) is performed based on these settings.

[Operation]

The registers 21, 22, 23, and 24 in this invention are set to any given value by the program, and the memory (RAM 1) is accessed based on the various settings that have been set, at which time test data is written to the memory and read from the memory. The data written as this test data, and the data that is read, are compared to each other for each of the access operations that are based on the respective settings, and when the data that is written to the memory (RAM 1) matches the data that is read from the memory, then the settings are set as the final settings in the registers 21, 22, 23, and 24, and after that time the access timing is determined based on these final settings and the memory (RAM 1) is accessed with that access timing when the specific data write and data read operations are performed.

[Example of Embodiment]

An Example of Embodiment of this invention is explained below based on the figures. Figure 1 is a block diagram of logic circuits that use the method for setting the memory access timing in this Embodiment of the invention. In Figure 1 the same symbols are used as corresponding to the structural elements shown in Figure 6, so the explanations are omitted here. In Figure 1, 21 is the register for determining the timing with which the RAS signal is produced (hereinafter termed the "RAS register"), 22 is the register for determining the timing with which the COLS signal is produced (hereinafter termed the "COLS register"), 23 is the register for determining the timing with which the CAS signal is produced (hereinafter termed the "CAS register"), 24 is the register for determining the timing with which the memory access complete signal will be produced (hereinafter termed the "CPLT register"), 25, 26, 27, and 28 are the selectors that select one output from output T0 to Te of the e + 1 registers in memory control ring 6.

Next the operation will be explained. Let us assume that there are five different types of RAM that can be obtained, and, the access timing on these types of RAM, from fastest to slowest, are RAM₁, RAM₂, RAM₃ RAM₄, and RAM₅. The respective RAMs can be accessed correctly by outputting the RAS signals, COLS signals, CAS signals, and memory access complete signals shown in the timing diagram of Figure 2. The explanation described below considers the operations when RAM₂ is installed.

The table has the settings for the RAS register 21, the COLS register 22, the CAS register 23, and the CPLT register 24, or in other words, the settings for k1 to k5, ll to 15, ml to m5, and nl to n5 in Figure 2, are stored as a table. This program executes the flow chart shown in Figure 3. In other words, the program is executed (Step S1), the pointer indicates RAM1 (Step S2), the information indicated by the pointer (in this case, the settings k1 corresponding to RAM1 shown in Figure 2) are loaded into RAS register 21 (Step S3), the pointer is then incremented (Step S4), the information indicated by the pointer (in this case, the setting 11 corresponding to RAM₁) is loaded into the COLS register 22 (Step S5), the pointer is incremented (Step S6), the information indicated by the pointer (in this case, the setting m1 corresponding to RAM1) is loaded into the CAS register 23 (Step S7), the pointer is incremented (Step S8), the information indicated by the pointer (in this case the setting n1 corresponding to RAM1) is loaded into the CPLT register 24 (Step S9), the pointer is incremented (Step S10), the test data is written into the RAM2 (because in this case it is RAM2 that is installed) (Step S11), and the write operation is performed with the timing shown in Figure 4. Then the data is read from the RAM2 with the timing shown in Figure 5 (Step S12), and the data that was read is compared to the data that was written (Step S13). In this case, the settings are the settings k1, l1, m1, and n1 that correspond to RAM₁. These settings do not match the timing for the control signals (the RAS signal, the COLS signal, the CAS signal, and the memory access complete signal) for RAM₂, so the comparison in Step 13 of the data that was read and the data that was written does not indicate a match with this timing. As a result, the program continues to Step S14, and a check is made for a pointer error. If there is an error then an error report is made (Step S15), and if there is no error, then the program returns to Step S3.

The information indicated by the pointer when the program returns to Step S3 is the setting k2 that corresponds to the RAM2 that is installed, and this setting k2 is loaded into the RAS register 21. After that, the same process that is described above is performed (Steps S4 through S10) and the setting 12 is loaded into the COLS register 22, the setting m2 is loaded into the CAS register 23, the setting n2 is loaded into the CPLT register 24, the test data is written to the RAM2 (Step S11) the data is read from the RAM₂ (Step S12), and the data that was written is compared to the data that was read (Step 13). In this case, the RAM access timing is set so that, when the operations for writing and reading the specified data are performed, the settings k2, 12, m2, and n2 correspond to RAM2, and thus RAM2 is accessed with the appropriate timing and the data that was read matches the data that was written so the program continues to Step 16 and the settings k2, g2, m2, and n2 are set into registers 21, 22, 23, and 24 as the final settings, and selectors 25, 26, 27, and 28 cause the RAS signal to be "1" when the output Tk2 + 1 of the memory control ring 6 is "1," the COLS signal to be "1" when the output Tl2 + 1 is "1," the CAS signal to be "1" when the output Tm2 + 1 is "1," and the memory access complete signal to be "1" when the output Tn2 is "1." In addition, when the output Tn2 + 1 is "1" the RAS signal, the COLS signal, the CAS signal and the memory access complete signal all go to "0."

While the explanation of the flow chart was based on the assumption that RAM 2 was installed, if RAM₁, RAM₃, RAM₄, or RAM₅ were installed instead, the processes in Steps 3 through 13 would be performed once, three times, four times, or five times, respectively, to set the access timing.

Because in the Example of Embodiment described above, it is possible to change the access timing using a program, it is easy to perform RAM access timing margin tests. In addition, although the timing will be that for the type of RAM with the slowest access time, even if a mixture of RAMs with different access times are installed in the logic circuits, the RAM can still be accessed correctly. In addition, if in high-speed computers, the RAM access timing is set individually by the card unit or the bank unit of main memory, then even if the type of RAM is different on different card units or bank units, the timing can be performed to match the capability of the RAM, making it possible to prevent any impediments to performance by mixing types of RAM. Additionally, in the program that determines the settings, it is possible to set the access timing that is optimized for the RAM that is installed and that is able to fully exploit the capabilities of the RAM through selecting the optimal values through changing the settings in even finer increments, rather than determining the settings in such a way as to compensate for the minor timing differences between the various RAM manufacturing locations. If in the program access timing setting checks are

performed for all addresses of all RAM, then it is possible to identify the RAM that has errors even if different types of RAM (with different access times) are mixed.

Furthermore, in the Example of Embodiment described above, dynamic RAM was used as the example, when static RAM is used then the chip select (CS) signal and the output enable (OE) signal can be controlled instead of the RAS signal and the CAS signal. Although in the Example of Embodiment above a memory control ring was used to control the RAM access timing, the method of this invention can also be performed by establishing for each signal to be controlled by the program a combination of a counter into which data can be loaded and a register that sets the value that is loaded into the counter as the initial value.

[Effects of the Invention]

Using the invention described above, it is possible to set the memory access timing automatically without a manual intervention because a register is provided wherein a variety of different values can be set by the program where the values that are set into this register are repetitively changed sequentially, test data is written to the memory and then read from the memory, and the data that was written is compared to the data that is read and the values that were set when the results of the comparison indicate a match are set to the register so that the memory is accessed based on those settings, it is able to prevent any disruptions to memory performance or situations where access cannot be performed normally due to incorrect settings in the access timing, making it possible to fully exploit the capabilities of the memory, and thus possible to obtain the effect of increased reliability; in addition, it is no longer necessary to have a manual intervention in order to set the access timing using jumper lines as it has been conventionally, thus making it possible to reduce operating test expenses and reduce labor expenses, and making it possible to provide data processing equipment less expensively.

4. Simple Explanation of Figures

Figure 1 is a block diagram of the logic circuits that use the method for setting the memory access timing in the Example of Embodiment of this invention.

Figure 2 is a timing diagram showing the relationship between the settings and the access timing in this Example of Embodiment.

Figure 3 is a flow chart used for explaining the operation of the Example of Embodiment.

Figure 4 is a timing chart for explaining a conventional example and explaining the operations for writing to the RAM in the Example of Embodiment thereof. Figure 5 is a timing chart for explaining the conventional example and for explaining the operations for reading from the RAM in an example thereof. Figure 6 is a block diagram of the logic circuits that use the conventional method of setting the memory access timing.
